Brain Imaging for Brain Disorders

Capture the brain structure and function changes associated with major brain-related disorders and normal development

Normal

AD

Alzheimer's disease (AD) is associated with brain shrinkage

Normal

AD

Most major brain disorders (like AD) are **heritable complex traits/diseases**

75%-90% of ADHD risk

~80% of Autism Spectrum Disorder (ASD) risk

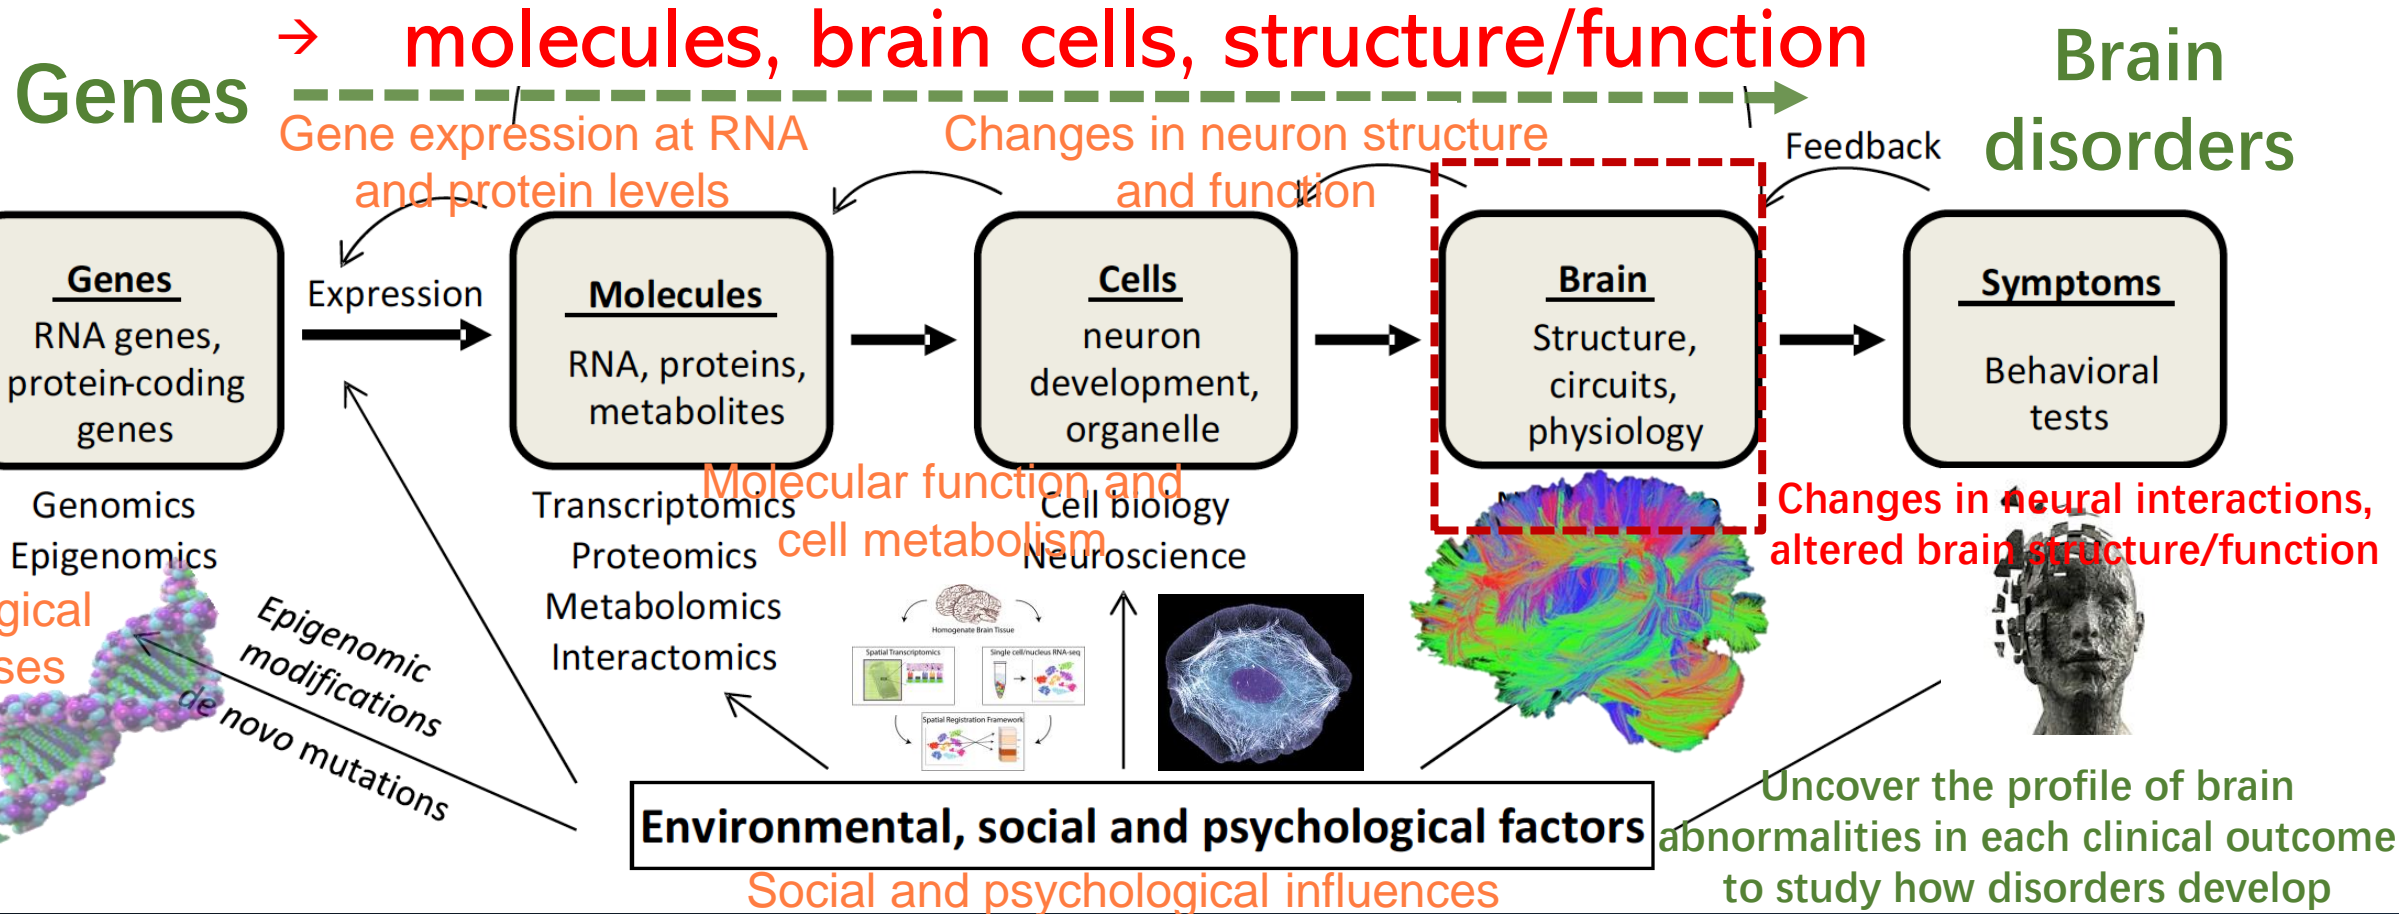

Genetic signals are non-sparse
and weak:
Need large sample size to
detect weak signals

Brain Imaging Genetics Paradigm

Neuroimaging: an important component to help understand the complex biological pathways of brain disorders

“Big Data” Imaging Cohorts

“Big data” Brain imaging datasets become available in recent few years

Systematically collect publicly available individual-level data for > 120k individuals

Build the largest database in this field

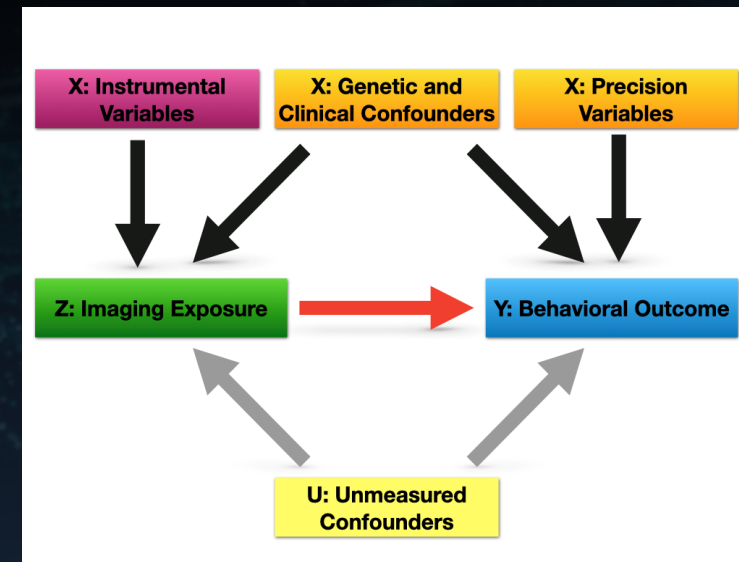

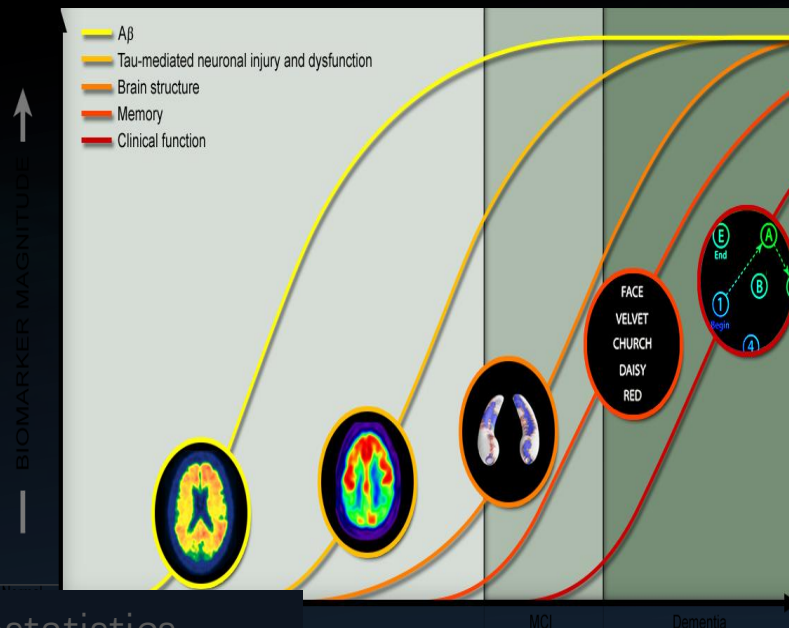

BCP (Age [0,5])	PING (Age [3,21])	ABCD (n ~ 10k, Age [9,11])	PNC (Age [14,29])	HCP (Age [22,35])	UK Biobank (n ~ 100k [Ongoing], Age [40,69])	RADC (Age > 65)
HBCD (Age [0,10])	HCP-D (Age [5,22])	IMAGEN (Age [14,22])		NACC (Age [36+])	HCP-A (Age [36+])	ADNI (Age [55,92])

Why Imaging Traits?

For a heterogeneous, clinically defined disorder, the endophenotype (or imaging traits) is 'closer to the underlying biology,'

- Be reproducible and heritable.
- Being informative about disorder risk.
- Providing mechanistic connections linking genetic variation to clinical measures.
- Some imaging traits (or brain circuits) may be treatable (e.g., ECT, TMS).
- Increasing the power of genetic search for **polygenic genetic architecture**.

Brain Imaging Modality Examples

Harmonize tools/pipelines to consistently generate the full spectrum of neuroimaging features

Cortical and subcortical structures

White matter microstructure
(Structural connectivity,
diffusion MRI)

Functional networks
(Functional connectivity,
functional MRI)

APOE-associations across functional networks

observations: 1) Enriched in the secondary visual and default mode networks;
2) Stronger connections in fMRI than in structural MRI.

It's just a beginning

IG: Reproducibility and Heritability

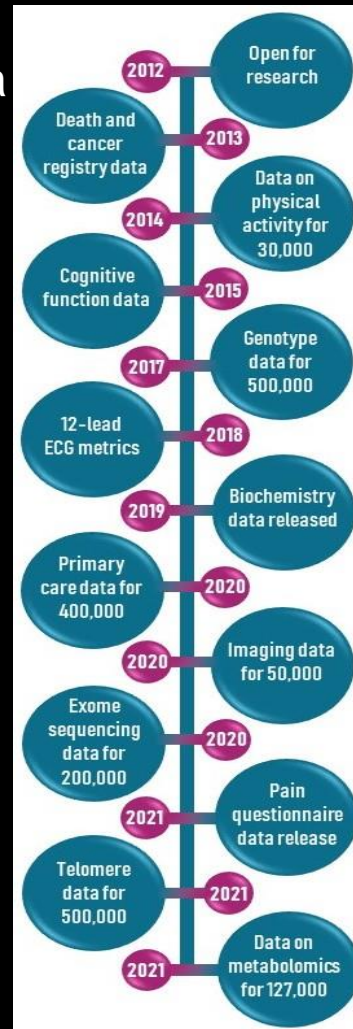

The UK Biobank Study

UK Biobank has collected and continues to collect extensive environmental, lifestyle, and genetic data on half a million participants.

2006-now

• **Imaging:** Brain, heart and full body MR imaging, plus full body DEXA scan of the bones and joints and an ultrasound of the carotid arteries. The goal is to image 100,000 participants, and to invite participants back for a repeat scan some years later.

• **Genetics:** Genotyping, whole exome sequencing & whole genome sequencing for all participants.

• **Health linkages:** Linkage to a wide range of electronic health-related records, including death, cancer, hospital admissions and primary care records.

• **Biomarkers:** Data on more than 30 key biochemistry markers from all participants, taken from samples collected at recruitment and the first repeat assessment.

• **Activity monitor:** Physical activity data over a 7-day period collected via a wrist-worn activity monitor for 100,000 participants plus a seasonal follow-up on a subset.

• **Online questionnaires:** Data on a range of exposures and health outcomes that are difficult to assess via routine health records, including diet, food preferences, work history, pain, cognitive function, digestive health and mental health.

• **Repeat baseline assessments:** A full baseline assessment is undertaken during the imaging assessment of 100,000 participants.

• **Samples:** Blood & urine was collected from all participants, and saliva for 100,000.

Multiorgan Dysfunction Syndromes

Imaging: help understand the complex interplay between brain and other human organs and their underlying genetic overlaps

Possible causal factors of brain structure changes, resulting in brain disorders like stroke, dementia and cognitive impairment

Many diseases (e.g., microvascular disease, high blood pressure) are multisystem disorders

The Brain-Heart Axis

The brain-heart axis refers to the bidirectional communication between the brain and the heart, playing a crucial role in regulating physiological functions and maintaining overall health.

Neural Regulation:

- **Autonomic Nervous System (ANS):** regulate heart rate, blood pressure, and cardiac output.
- **Vagus Nerve:** reduce heart rate and promoting relaxation.

Endocrine Pathways:

- **Hypothalamic-Pituitary-Adrenal (HPA) Axis:** Influences heart function through the release of hormones, affecting blood pressure and cardiovascular health.
- **Catecholamines:** Adrenaline and noradrenaline released during stress increase heart rate and cardiac output.

Blood Flow and Oxygen Supply:

- **Cerebral Perfusion:** The heart ensures a continuous supply of oxygenated blood to the brain, essential for cognitive functions and neural health.
- **Cerebral Autoregulation:** Mechanisms that maintain stable blood flow to the brain despite changes in systemic blood pressure.

The Brain-Heart Axis

Disease Interactions:

- **Cardiovascular Diseases:** Conditions like atrial fibrillation and heart failure are linked to brain diseases such as stroke, dementia, and cognitive impairment due to reduced cerebral perfusion.
- **Mental Disorders:** Mental illnesses, including schizophrenia, bipolar disorder, epilepsy, and depression, increase the risk of CVD.

Acute Mental Stress:

- **Impact on Cardiovascular Health:** Acute stress can cause vascular inflammation and increase the risk of atherosclerosis due to stress-induced leukocyte migration.

Research Significance:

- **Integrated Treatment Approaches:** Lead to better treatments for neurocardiological disorders.
- **Comprehensive Studies:** A need for larger studies to provide a complete picture of the structural and functional links between heart and brain health.

Mental health issues-induced behavioral and biological processes

(For example, smoking initiation and dysregulation of the autonomic nervous system, Levine et al. (11), PMID: 33486973)

(A)

The Brain-Eye Axis

The **brain-eye axis** refers to the complex and interconnected relationship between the brain and the eyes, essential for visual perception, processing, and overall neurological function.

Anatomical Connections:

- **Optic Nerve:** The **optic nerve** transmits visual information from the retina to the brain's visual centers.
- **Retina as a Brain Extension:** The **retina** contains photoreceptor cells that detect light and initiate vision.

Visual Processing:

- **Primary Visual Cortex (V1)** in the occipital lobe. V1 processes visual information received from the eyes.
- **Higher Visual Areas:** For object recognition, spatial awareness, and motion detection.

Eye Movements and Brain Function:

Oculomotor Control: Eye movements are controlled by cranial nerves (III, IV, VI). **Attention and Cognition:** The brain coordinates eye movements.

Feedback Loops:

- **Top-Down Control:** The brain modulates visual processing based on contextual information, attention, and experience.
- **Autonomic Regulation:** The brain regulates the pupil and lens to control how much light enters the eye and focuses on objects at different distances.

(A)

The Brain-Eye Axis

Health and Disease

Neurodegenerative Diseases: Changes in the retina and optic nerve can be early indicators of neurological diseases like Alzheimer's, Parkinson's, and multiple sclerosis.

Visual Disturbances: Conditions like glaucoma, optic neuritis, and retinal degeneration affect both vision and brain function, showing how interdependent the brain and eyes are.

Stroke and Vision: Strokes that affect the brain's visual pathways can lead to visual field defects and other disturbances.

Clinical Relevance

Diagnostics: Eye health and retinal imaging can serve as non-invasive markers for detecting brain health, especially in diseases like Alzheimer's and multiple sclerosis.

Neuro-Ophthalmology: This field bridges neurology and ophthalmology, focusing on conditions that affect both the brain and eyes, such as optic neuropathies and visual processing disorders.

Evaluating and Sharing Pipelines

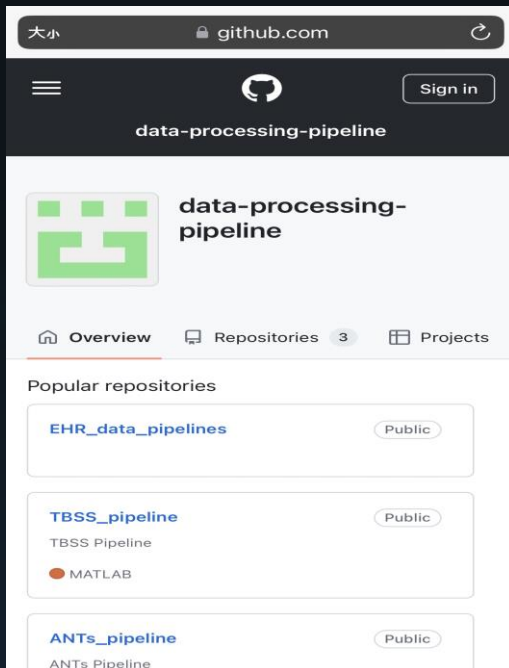

More good data processing pipeline papers

<https://github.com/data-processing-pipeline>

➤ Good datasets for comprehensive evaluation. There is no publicly available, high-quality imaging datasets with detailed annotation information that cover a large spectrum of segmentation tasks in health care.

➤ How to quantify the uncertainty and generalizability of brain atlas as well as segmentation and registration tools?

➤ How to develop foundational models for various segmentation and registration tasks?

Part III

Highly Efficient Imaging Genetic Methods

“Statistical methods become truly impactful when they are not just about fitting models, but about driving discovery—by making complex imaging data interpretable, reproducible, and applicable in clinical practice.

- *chatGPT*-

Brain Imaging Genetics Data Analysis

Association tests

Identify and replicate novel genetic factors associated with brain structure and function

Causal inference/ Mediation analysis

Analyze the genetic links among brain structure, brain function, cognition, and major brain disorders.

Data integration

Integrate external genetics/genomics data (e.g., the GTEx, Hi-C chromatin interactions) to uncover new biological insights

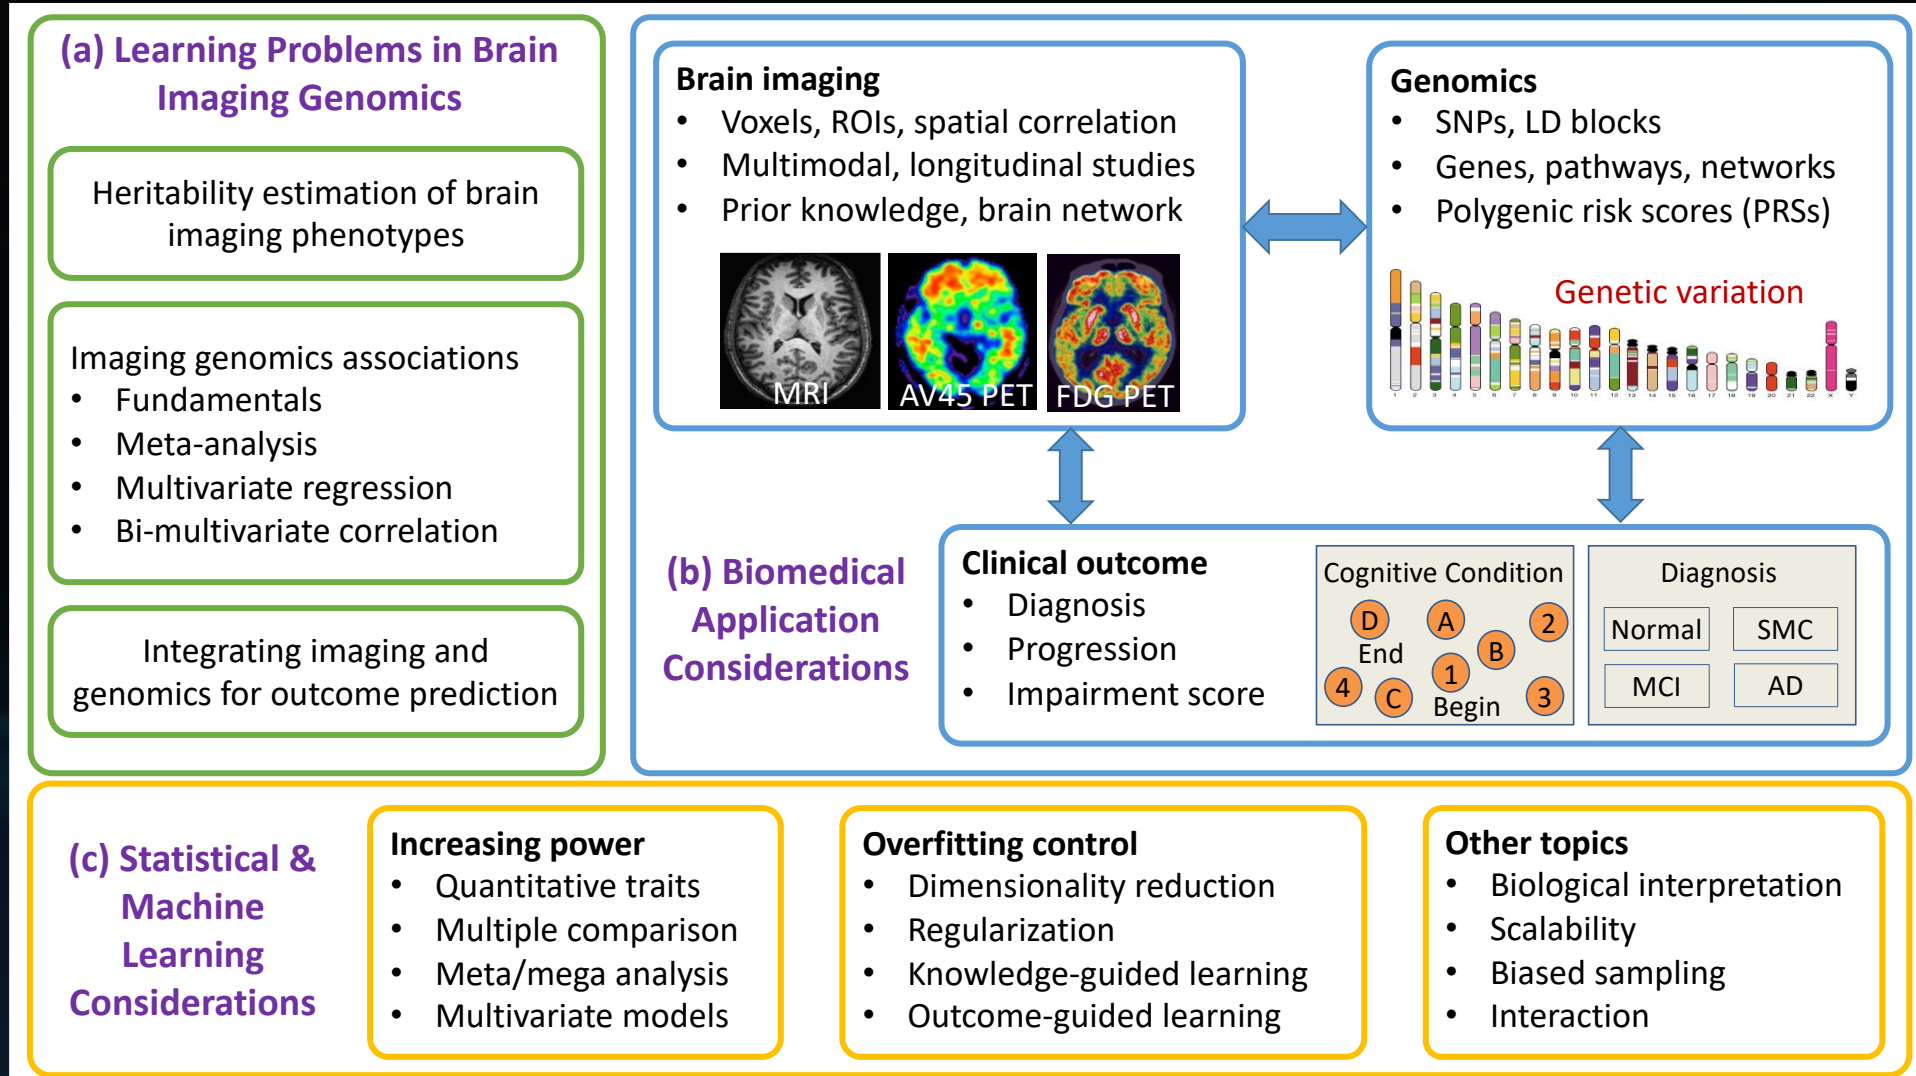

Predictive model

Perform out-of-sample risk prediction for brain disorders using genetics, genomics, and imaging data

- 1) Output high-quality novel clinical findings
- 2) Identify, model, and address important statistical problems
- 3) Share our summary-level data/results to the research community

Brain Imaging Genetics: Learning Problems

Imaging-derived phenotypes (IDPs)

- Parcellating the human brain based on predefined atlases; aggregating voxels within each ROI (e.g., taking average)
 - Restricted by atlas
 - Removed local variations
- Conducting independent component analysis (ICA); extracting components as phenotypes
- Extracting features from deep learning models (e.g., Autoencoder)
 - Difficult to interpret the connection between the human brain and genetic markers

**Missing localized genetic architecture
in brain structure and function**

Neuroimaging Genetic Knowledge Portals

What is **ENIGMA**?

The **ENIGMA Consortium** brings together researchers in imaging genomics to understand brain structure, function, and disease, based on brain imaging and genetic data. We welcome brain researchers, imagers, geneticists, methods developers, and others interested in cracking the neuro-genetic code!

10000x50\$=0.5M\$; 0.1Mx50\$=5M\$; 1Mx50\$=50M\$

Challenges in Voxel-level GWAS

- **Computationally intractable**
 - High dimensionality of both imaging ($10^4 \sim 10^6$) and genetic data (10^8)
- **Difficult to share summary statistics**
 - The data volume can be 100 times larger than the current size of GWAS catalog
- **Multiple comparison in hypothesis testing across voxels**
 - Voxels are highly correlated
- **Noises in imaging data**
 - Reducing statistical power and reliability
 - Intensifying challenges in identifying genetic architectures underlying brain structures and functions

Current Solutions & Limitations

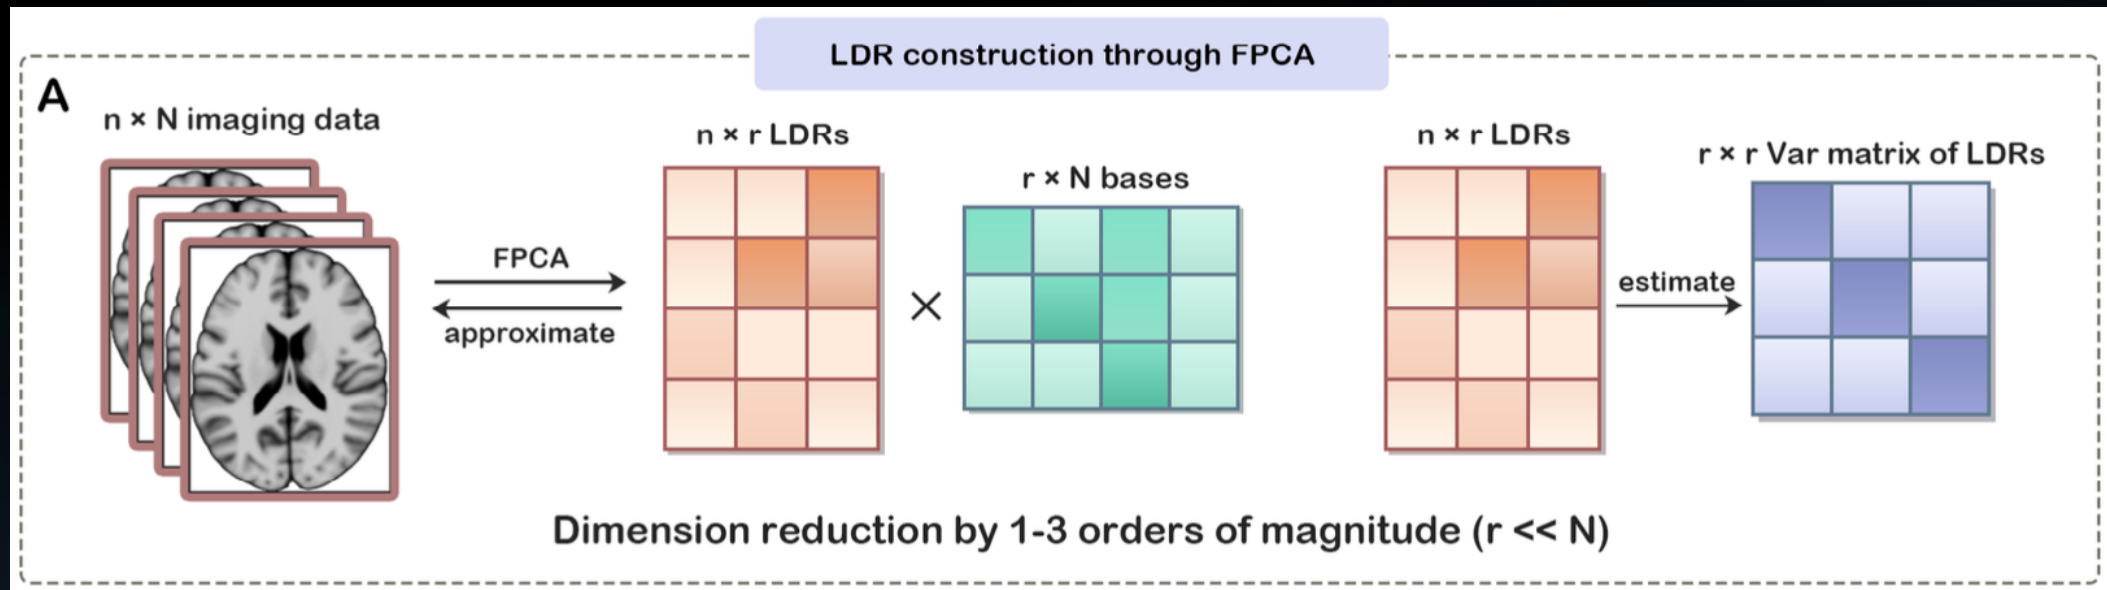

- Considering multiple genetic markers simultaneously
- Screening candidate markers
- Using rank-reduction or Bayesian techniques

Cannot generate whole-genome summary statistics needed for secondary analyses

- Voxel/local heritability
- Genetic correlation between voxels and with other phenotypes
- Colocalization analysis
- Mendelian randomization

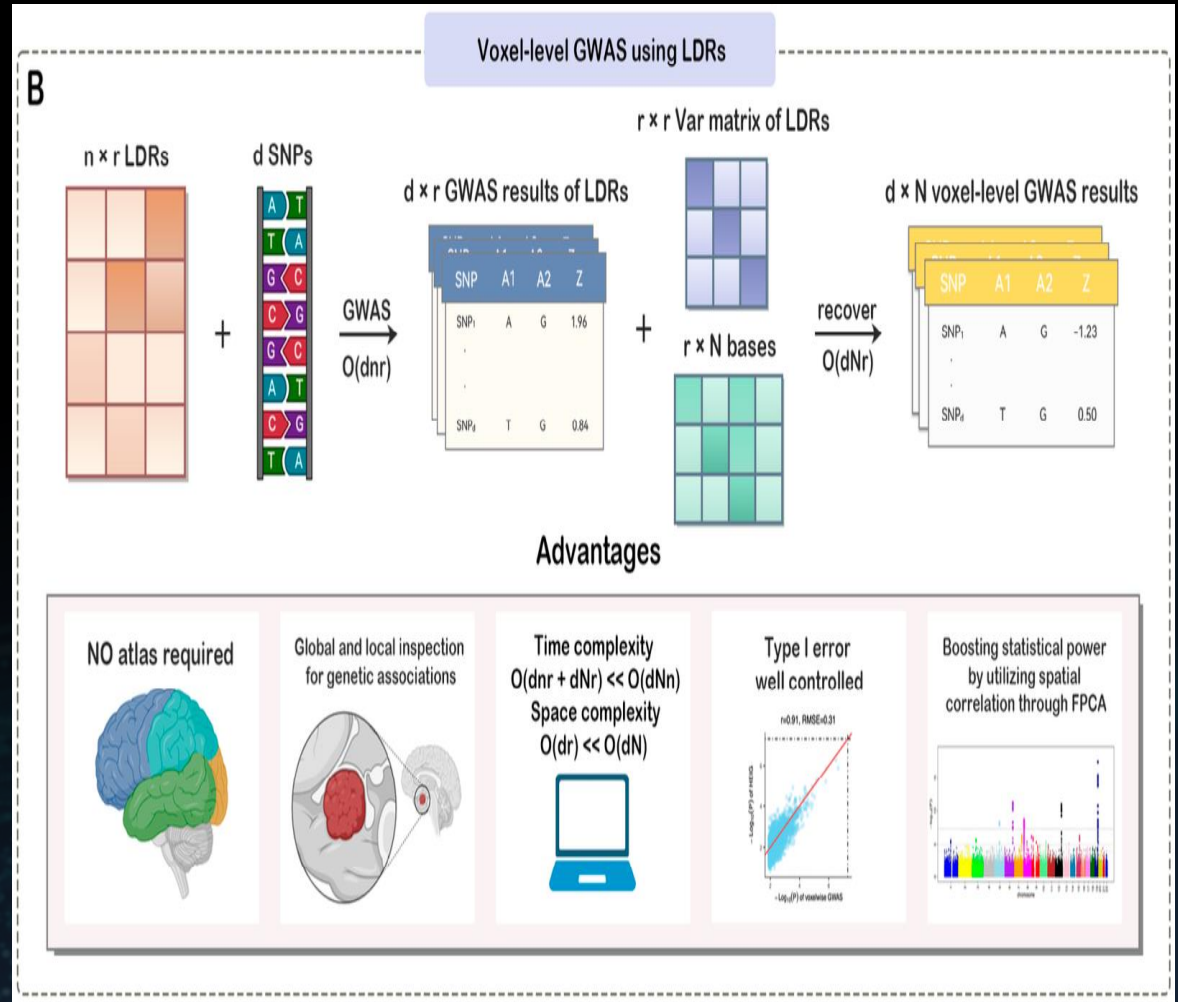

Highly efficient imaging genetics (HEIG)

- Using functional PCA (or other DR methods) to derive low-dimensional representations (LDRs)
- Dimension reduction by 2-3 orders of magnitude
- Removing white noise while preserving majority of imaging signals

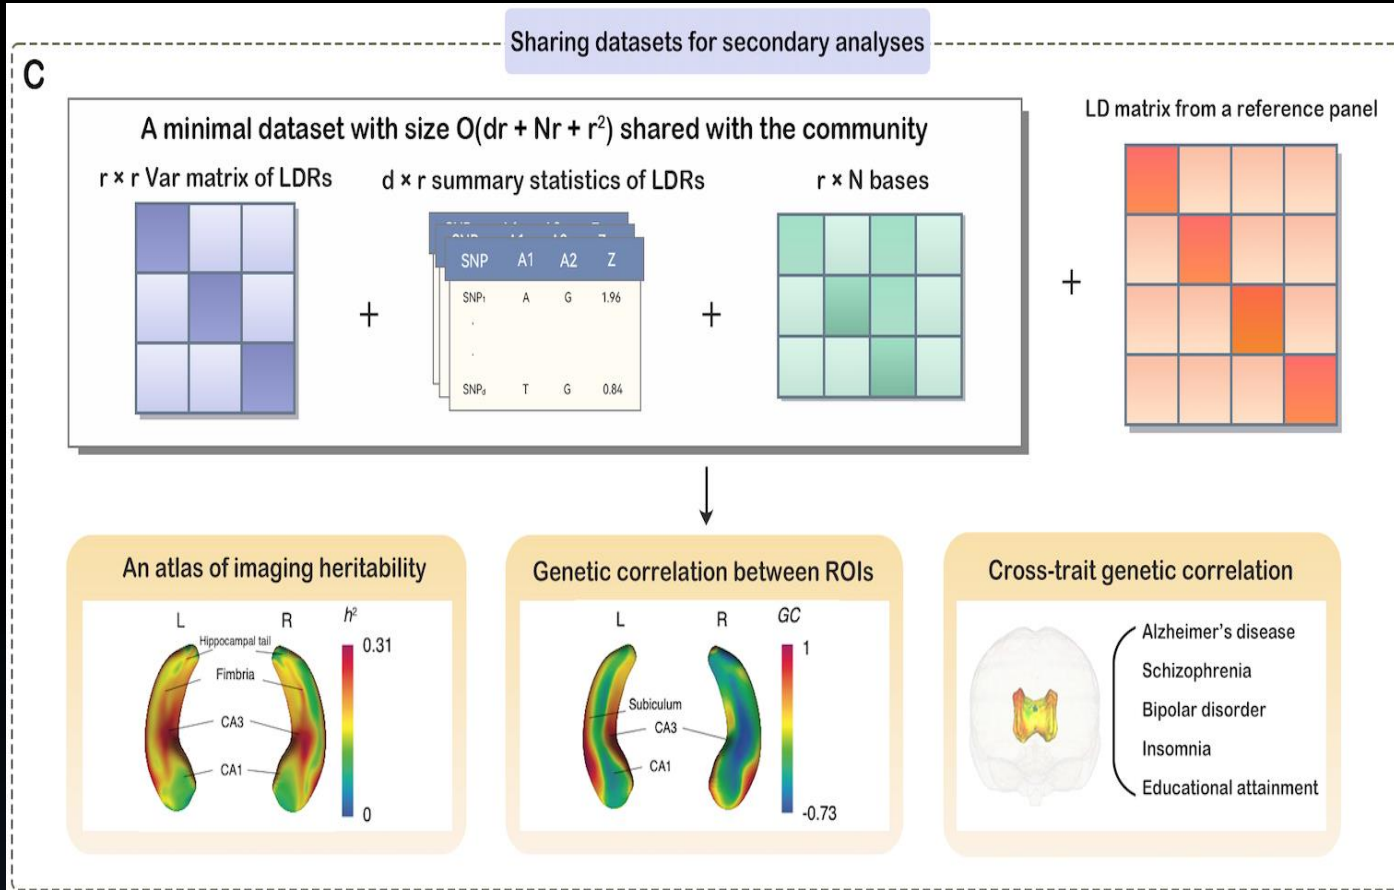

Highly efficient imaging genetics (HEIG)

- Conducting GWAS on LDRs and reconstructing voxel-level summary statistics
- Global and local inspection for genetic associations without atlas
- Reducing time and memory consumption by over 100 times
- Effectively protecting the type I error and boosting statistical power
- Using the effective number of independent voxels to adjust for multiple comparison

Highly efficient imaging genetics (HEIG)

- Sharing minimal datasets with the community for all secondary analyses
- Proposing a unified estimator to investigate voxel heritability, genetic correlation between voxels, and cross-trait genetic correlation between voxels and non-imaging phenotypes

Real data analysis

Input data

- UK Biobank 33,324 unrelated European subjects
- Hippocampus shape (15,000 vertices in each of left and right hemispheres)
- White matter (WM) microstructure (21 tracts, from 88 to 3,503 voxels, 32,217 in total)
- Surface curvature (the whole brain, 59,412 vertices)
- Genetic data: 7.8 million common variants

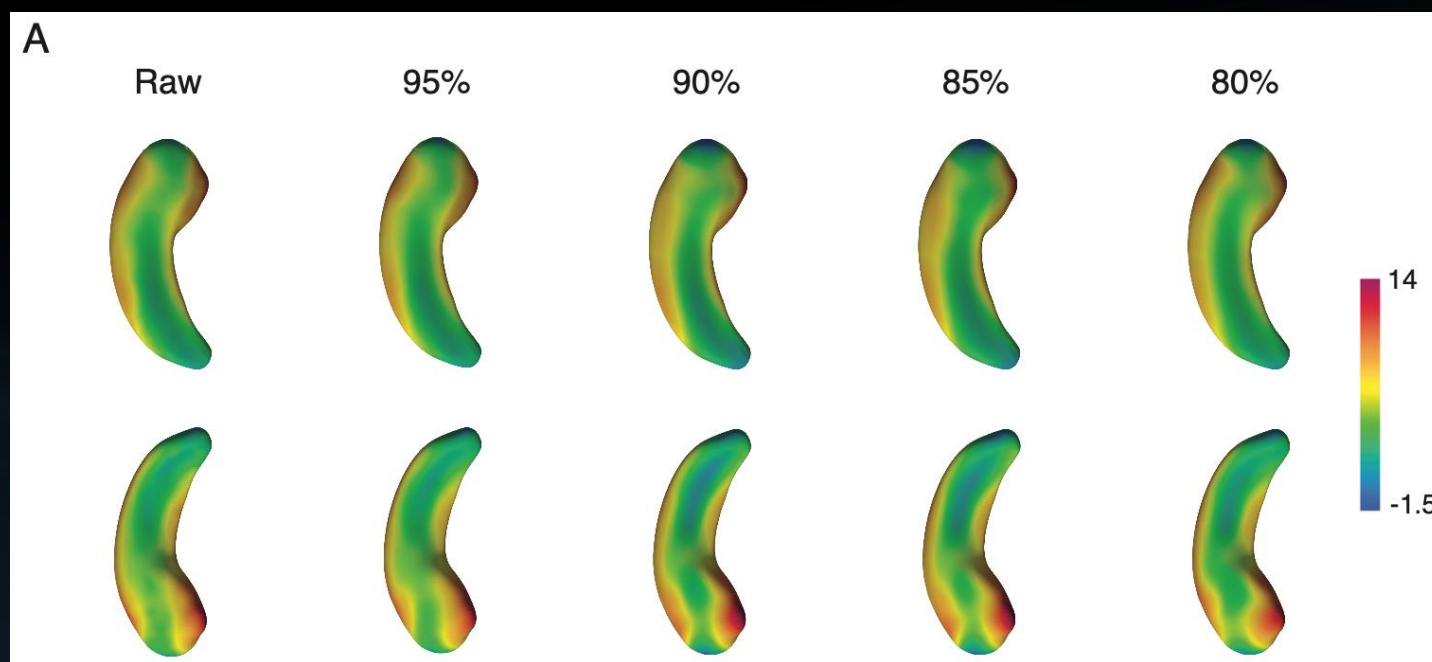

Constructing low-dimensional representations (LDRs)

- Hippocampus shape: 25 (0.13%) LDRs
- WM microstructure: 49 (4.1%) LDRs
- Surface curvature: 1,750 (2.9%) LDRs
- Using only 49, 1,034, and 1,750 LDRs to capture signals in 30,000, 32,217, and 59,412 voxels/vertices, respectively

Real data analysis

High correlation between the raw and reconstructed images using LDRs

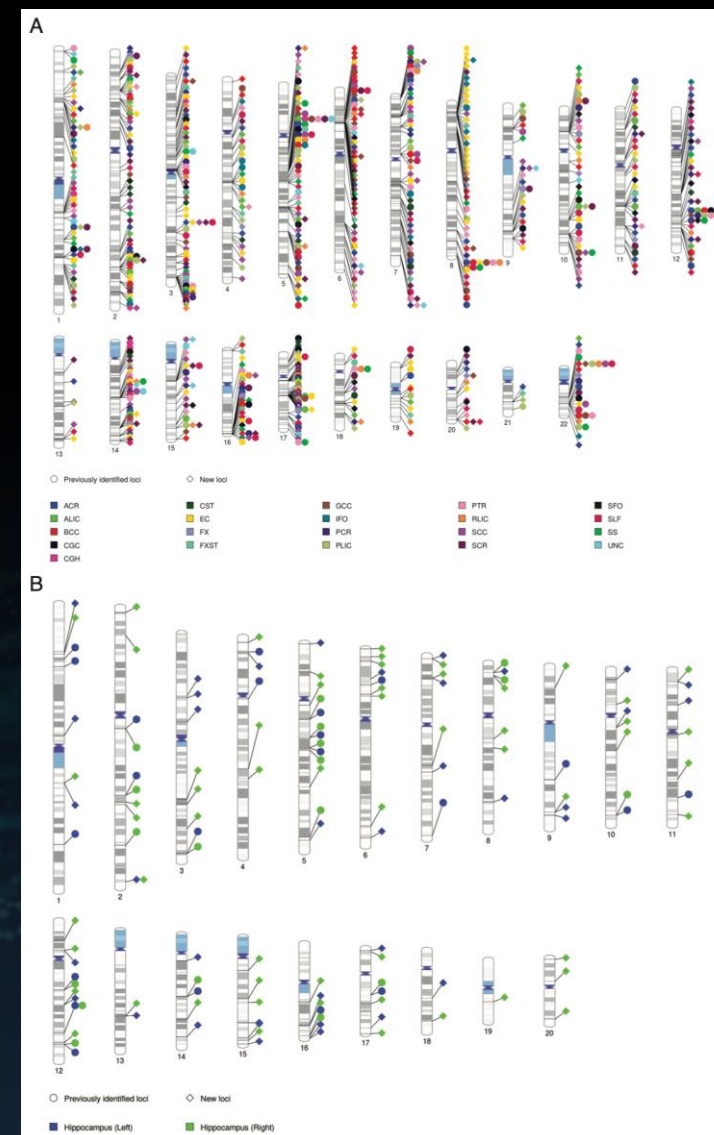

- Hippocampus shape: 0.93 with 25 (0.13%) LDRs
- WM microstructure: 0.86 with 49 (4.1%) LDRs
- Surface curvature: 0.85 with 1,750 (2.9%) LDRs

Real data analysis

Voxel-level GWAS – hippocampus and WM microstructure

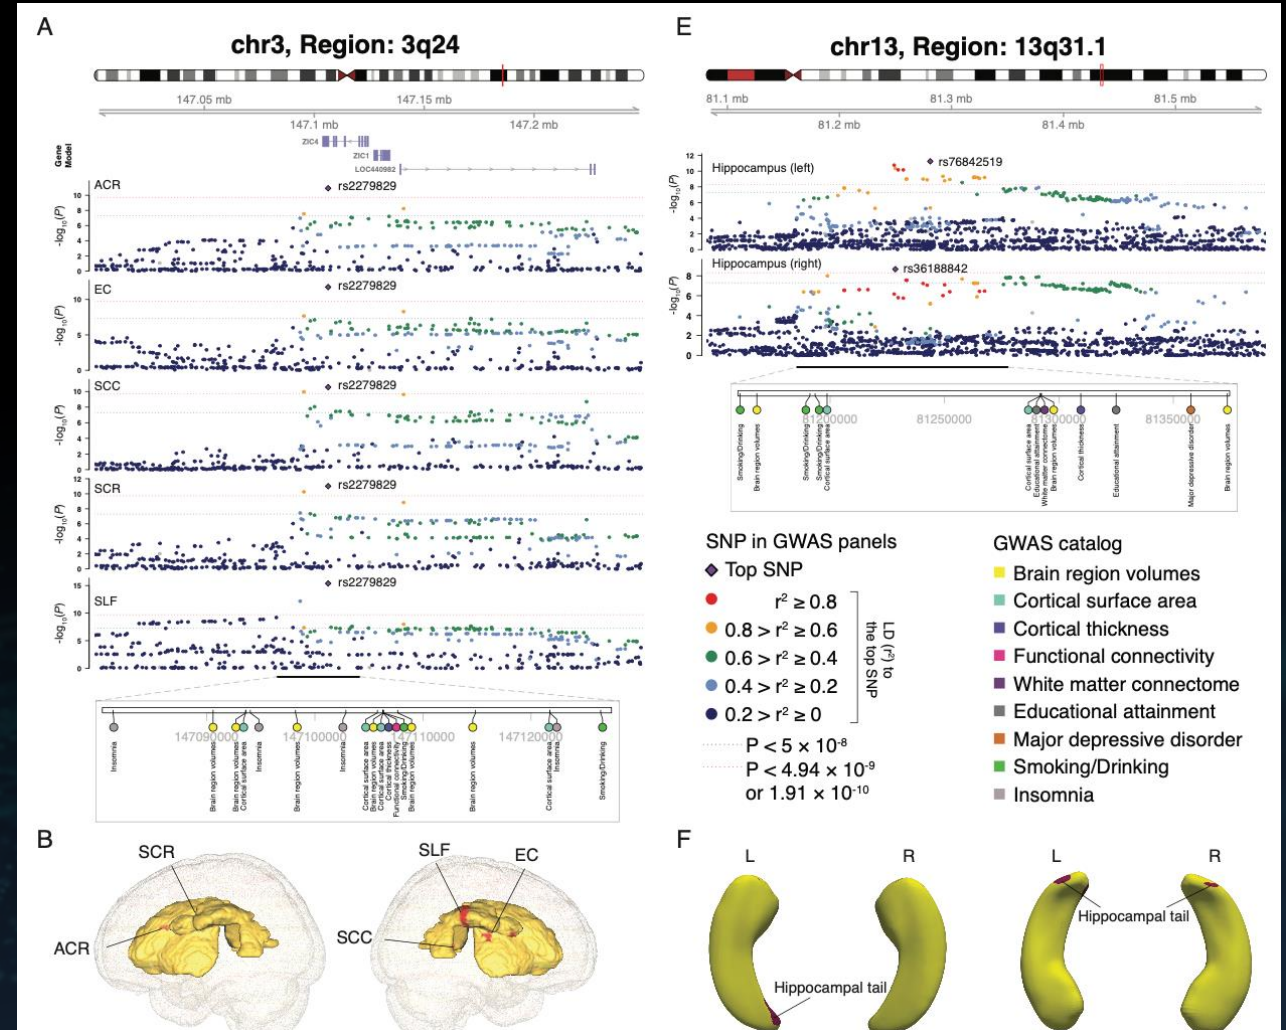

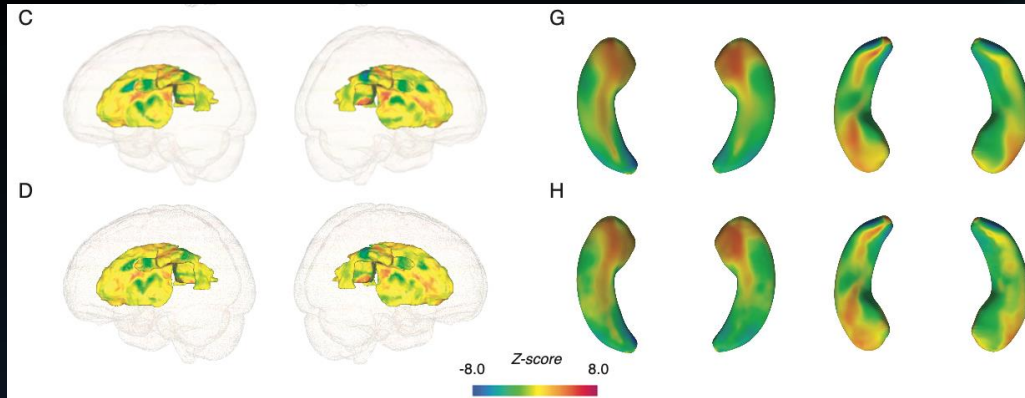

- GWAS on 1,083 LDRs generated 95 GB of data, 133 times less than storing every voxel-variant pair (12,611 GB)
- Identified 815 significant loci, of which 94 and 540 are novel for hippocampus shape and WM microstructure, respectively, compared to IDP-based studies
- In a replication study (n=6,168), 39% of loci can be replicated
- Consistent with GWAS on voxels (raw data), but boosting statistical power for significant associations

Real data analysis

Voxel-level GWAS

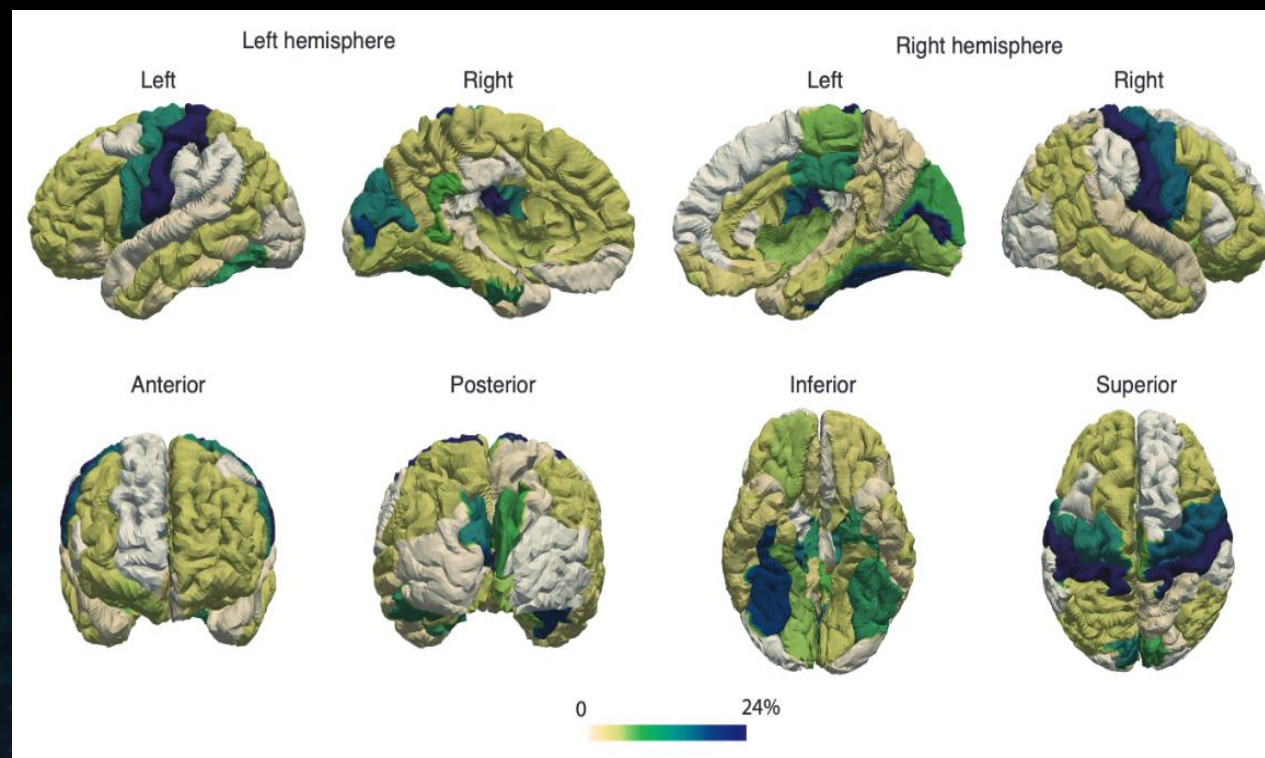

- Discovered novel loci and colocalizations with brain-related phenotypes including insomnia, major depressive disorder, and smoking/drinking
- Z-score correlation = 0.98 with GWAS directly on voxels

Real data analysis

Voxel-level GWAS – surface curvature

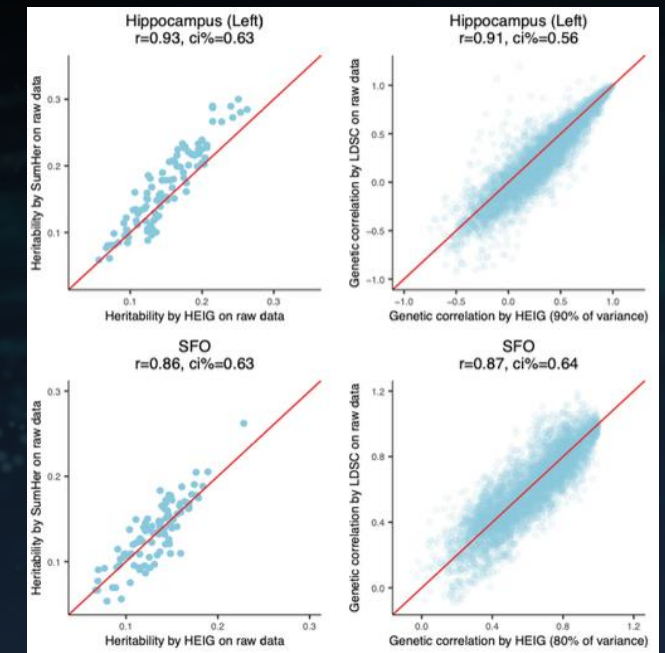

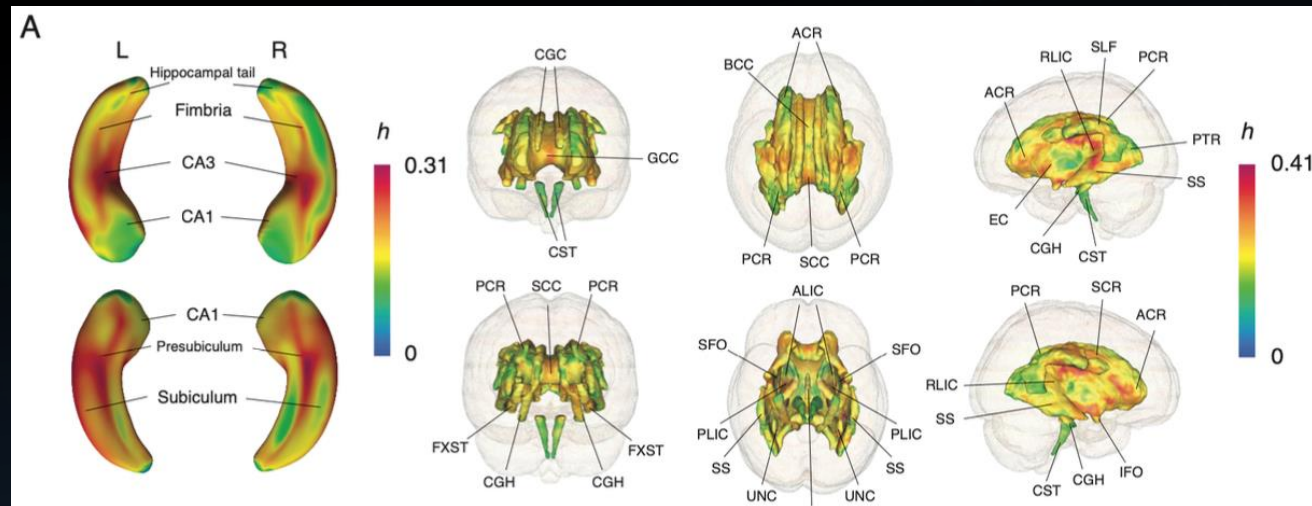

- GWAS on 1,750 LDRs generated 87 GB of data to share, 138 times less than storing every vertex-variant pair (12,042 GB)
- Identified 1,431 significant loci, of which 912 (63.7%) were replicated (n=12,431)
- Postcentral and precentral regions were enriched with significant vertices associated with at least one SNP

Real data analysis

Voxel heritability and genetic correlations

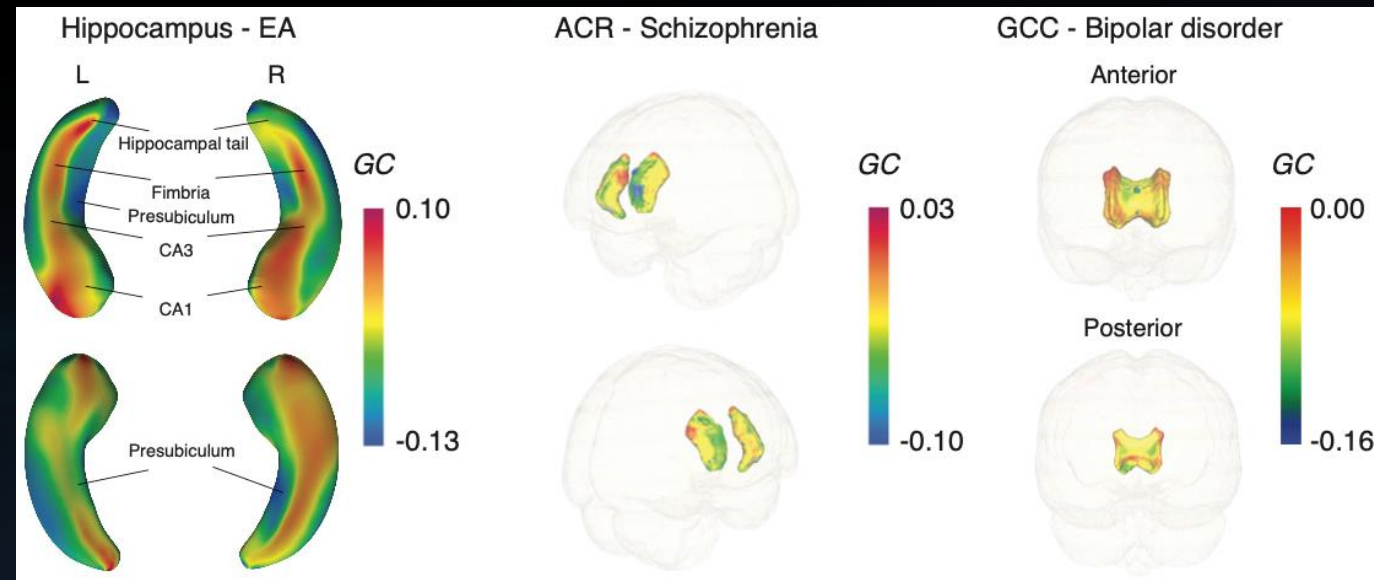

- Constructed an atlas of heritability using LDR summary statistics and an LD matrix
- Identified shared genetic bases between subregions
- Highly consistent with SumHer in heritability estimates and with LDSC in genetic correlation estimates, despite distinct methodology

Real data analysis

Cross-trait genetic correlations with 14 brain-related phenotypes

- Hippocampus (presubiculum) with educational attainment (-13%, $P = 0.001$)
- Right anterior corona radiata with schizophrenia (-9%, $P = 4.3 \times 10^{-5}$)
- Genu of the corpus callosum with bipolar disorder (-16% ~ 0%, $se = 2.6\%$)

Computational efficiency

Comparing with REGENIE using 193 voxels, 33,324 subjects, and 7.8 million SNPs

- HEIG took 13 CPU hours and generated 4.1 GB of data for sharing
- REGENIE took 107 CPU hours and generated 127 GB of data of all variant-voxel pairs

Benchmarking study using the surface area data of the whole brain with 59,412 vertices, 15,752 subjects, and 7.8 million SNPs

- HEIG took 2.8 hours to construct 1750 LDRs (4 CPUs in parallel)
- GWAS for 1750 LDRs using REGENIE took 56 hours (16 CPUs in parallel)
- Voxel-level GWAS using HEIG took 32 hours (4 CPUs in parallel)
- Generated 87 GB of data for sharing
- HEIG took 20 minutes for estimating 59,412 vertex heritability and genetic correlation

Contributions

- Reducing time and storage consumption by 2-3 orders of magnitude
- Efficiently generating and sharing summary statistics for voxel-level analysis
- Enhancing statistical power and genetic influence by removing white noise
- Investigating genetic architectures underlying both global and local patterns in the human brain without predefined atlases
- Straightforward extension to other organs and high-dimensional datasets with strong correlation
